## Representation: Simplicial complex at an offset

《曰》 《聞》 《臣》 《臣》 三臣

Simplicial representation at offset  $F_{\alpha} \triangleq \{\sigma(\bigcup_{x \in P} B_{\alpha/2}(x))\}$ 

A filtration is a sequence of simplicial representations  $\mathcal{F} \triangleq (F_{\alpha_1}, F_{\alpha_2}, \cdots, )$  where  $\alpha_1 \leq \alpha_2 \leq \cdots$ .

Image: A math the second se

## Topological Features and Persistence

- As higher-order simplices appear (born) in the filtration,
  - new cycles may appear (new homology classes being born)
  - some cycles may vanish by becoming boundaries of higher-order simplices. (existing homology classes being merged with others)
- The birth and deaths of homology classes are represented in different ways: barcode, persistence diagrams etc.

## TDA pipeline: Summary

Figure 1: TDA pipeline

- Input Data: Point cloud, Graph.
- *Topological Representations:* Simplicial complex at offset. Mathematically: A vector space
- *Filtration:* Sequence of offset simplicial complexes. Mathematically: A sequence of vector spaces with canonical inclusion map defined by boundary operator.
- *Persistent Homology Class:* Inclusion maps induces linear maps in the homology vector spaces in the sequence. The image of these maps charecterizes the persistence (birth,death) of the homology classes in the sequence.
- Topological descriptors: Multiset of points in  $\mathbb{R}^2$  called persistence diagrams.

Computational Issues with simplicial Representations and approximate representations.

May 25, 2022

5 / 22

## Approximate Simplicial Representations

- Čech complex captures the actual topology of the underlying space.
  - *Issue:* computionally challenging  $\rightarrow$  at most  $O(n^k)$  simplices of dim. up to k.
- Vietoris-Rips Complex (R<sub>α</sub>) for a given offset α considers a simplex σ to be in R<sub>α</sub> if the distance between every pair of points in σ is at most <sup>α</sup>/<sub>2</sub>.
  - Good news: 2-approximation of the Čech complex in arbitrary metric space.

<ロト <四ト <注入 <注下 <注下 <

• Bad news: at most  $O(n^k)$  simplices of dimension up to k.

#### Computational bottleneck

Need to enumerate large number of simplices.

## Approximate Simplicial Representations

- Čech complex captures the actual topology of the underlying space.
  - *Issue:* computionally challenging  $\rightarrow$  at most  $O(n^k)$  simplices of dim. up to k.
- Vietoris-Rips Complex (R<sub>α</sub>) for a given offset α considers a simplex σ to be in R<sub>α</sub> if the distance between every pair of points in σ is at most <sup>α</sup>/<sub>2</sub>.
  - Good news: 2-approximation of the Čech complex in arbitrary metric space.
  - Bad news: at most  $O(n^k)$  simplices of dimension up to k.

#### Computational bottleneck

Need to enumerate large number of simplices.

#### Research Question

Can we have approximate simplicial representations which are computable in reasonable time, yet good approximations to Vietoris-Rips or Čech complex?

## A Computationally Faster Approximation: Lazy Witness Complex and The Question to Solve

#### Lazy witness Complex $LW_{\alpha}(P, L)$

Lazy witness Complex  $LW_{\alpha}(P, L)$  of a point-cloud P is a simplicial complex over a landmark set L containing simplices  $\sigma$  such that  $\forall v_i, v_j \in \sigma$ ,  $\exists w \in P$  with the following property:

$$\max\{d(w, v_i), d(w, v_j)\} \le \alpha + d(w, L)$$

here, d(w, L) is the distance from w to its closest point in L.

- Good news: Vietoris-Rips complex on landmarks is Lazy witness complex. The number of simplices in Lazy witness complex is O(|L|<sup>k</sup>) << O(|P|<sup>k</sup>) for |L| << |P|</li>
- Bad news: There is no approximation guarantee available for  $|L| \neq |P|$ . There is no algorithm that selects L with any approximation guarantee.

▲□▶ ▲□▶ ▲□▶ ▲□▶ = ● ● ●

# A Computationally Faster Approximation: Lazy Witness Complex and The Question to Solve

#### Lazy witness Complex $LW_{\alpha}(P, L)$

Lazy witness Complex  $LW_{\alpha}(P, L)$  of a point-cloud P is a simplicial complex over a landmark set L containing simplices  $\sigma$  such that  $\forall v_i, v_j \in \sigma$ ,  $\exists w \in P$  with the following property:

$$\max\{d(w, v_i), d(w, v_j)\} \le \alpha + d(w, L)$$

here, d(w, L) is the distance from w to its closest point in L.

- Good news: Vietoris-Rips complex on landmarks is Lazy witness complex. The number of simplices in Lazy witness complex is O(|L|<sup>k</sup>) << O(|P|<sup>k</sup>) for |L| << |P|</li>
- Bad news: There is no approximation guarantee available for |L| ≠ |P|. There is no algorithm that selects L with any approximation guarantee.

#### New Questions

How to select the landmarks? How good are the landmarks selected by an algorithm? Can we obtain any approximation guarantee for the lazy witness complex?

## Our Contributions

### The Central Concept

We respond to all these questions by reincarnating the idea of  $\epsilon$ -net in TDA.

- Q. Can we obtain any approximation guarantee for the lazy witness complex?
- -> Lazy witness complex induced by an  $\epsilon$ -net is a 3-approximation to the Vietoris-Rips complex (point cloud and connected unweighted graph).
- Q. How good are the landmarks selected by an algorithm?
- ->  $\epsilon$ -net is an  $\epsilon$ -approximation of the point cloud and graph vertices in Hausdorff distance.
- Q. How many landmarks are there in an  $\epsilon$ -net?
- -> For a connected unweighted graph of diameter  $\Delta$ , there exists an  $\epsilon$ -net of size at most  $(\frac{\Delta}{\epsilon})^{O(\log \frac{|V|}{\epsilon})}$ . (For point cloud it is known<sup>3</sup> to be  $(\frac{\Delta}{\epsilon})^{\Theta(D)}$ )
- Q. How to select the landmarks?
- -> polynomial-time algorithms to construct  $\epsilon$ -net on point cloud and on graphs.

#### $\epsilon$ -net

A subset L of points which is  $\epsilon$ -sparse and  $\epsilon$ -sample of point cloud P.

## $\epsilon$ -net for undirected graphs

#### Definition ( $\epsilon$ -sample)

A set  $L = \{u_1, u_2, \dots, u_{|L|}\} \subseteq V$  is an  $\epsilon$ -sample of graph  $G = (V, d_G)$  if the collection  $\{\mathcal{N}_{\epsilon}(u_i) : u_i \in L\}$  of  $\epsilon$ -neighbourhoods covers G i.e.  $\cup_i \mathcal{N}_{\epsilon}(u_i) = V$ .

#### Definition ( $\epsilon$ -sparse)

A set  $L = \{u_1, u_2, \dots, u_{|L|}\} \subset V$  is  $\epsilon$ -sparse if for any distinct  $u_i, u_j \in L$ ,  $d_G(u_i, u_j) > \epsilon$  in graph G.

7 / 22

## $\epsilon$ -net for undirected graphs

A graph G = (V, E)

 $\epsilon$ -sample

 $\epsilon$ -sparse

### Definition ( $\epsilon$ -net)

A subset  $L \subset V$  of vertices which is  $\epsilon$ -sparse and an  $\epsilon$ -sample of graph  $G = (V, d_G).$ 

# $\epsilon\text{-net}$ induced Lazy witness complex: Theoretical guarantees

9 / 22

May 25, 2022

## The meaning of approximation guarantee

Suppose  $\mathcal{F} = (F_{\alpha})_{\alpha>0}$  and  $\mathcal{G} = (G_{\alpha})_{\alpha>0}$  be two filtrations and their associated persistence diagrams at dimension k be  $Dgm(\mathcal{F})$  and  $Dgm(\mathcal{G})$ . Approximation is defined in terms of distance between persistence diagrams.

#### Definition (Bottlneck distance between diagrams)

$$d_B(Dgm(\mathcal{F}), Dgm(\mathcal{G})) \triangleq \inf_{\phi: Dgm(\mathcal{F}) \to Dgm(\mathcal{G})} \sup_{x \in Dgm(\mathcal{F})} \|x - \phi(x)\|_{\infty}$$

where  $\phi$  is a bijection between points in the diagrams  $Dgm(\mathcal{F})$  and  $Dgm(\mathcal{G})$ 

#### Definition ( $\delta$ -approximation between diagrams)

Let  $(\log \mathcal{F})_A$  be the re-parameterisation of  $(\mathcal{F})_A$  on the natural logarithm scale:

$$\log \mathcal{F}_A \triangleq \{\mathcal{F}_{e^{\alpha}}\}, \text{ for any } \alpha \in A$$

A persistence diagram  $Dgm(\mathcal{F}_A)$  is defined to be  $\delta$ -approximation to diagram  $Dgm(\mathcal{G}_B)$  if the following holds

$$d_B(Dgm(\log \mathcal{F}_A), Dgm(\log \mathcal{G}_B)) \leq \log(\delta)$$

We will use the following lemma<sup>4</sup> for our final result.

#### Lemma (Persistence Approximation Lemma)

If there exist  $\delta > 0$  such that the two filtrations  $(\mathcal{F})_{\alpha \geq 0}$  and  $(\mathcal{G})_{\alpha \geq 0}$  satisfy  $\mathcal{F}_{\alpha/\delta} \subseteq \mathcal{G}_{\alpha} \subseteq \mathcal{F}_{\delta\alpha}$  for all  $\alpha \geq 0$ , the persistence diagrams  $Dgm(\mathcal{F}_{\alpha})$  and  $Dgm(\mathcal{G}_{\alpha})$  are  $\delta$ -approximations of each other.

This lemma suggests that proving suitable interleaving between simplicial representations is sufficient to show approximation guarantee between the associated persistence diagrams.

<sup>4</sup>Donald R Sheehy. "Linear-size approximations to the Vietoris-Rips filtration". In: Discrete Computational Geometry 49.4 (2013), pp. 778-796.

#### Lemma (Interleaving)

If the landmark set L is an  $\epsilon$ -net of the point cloud P, the following interleaving of lazy witness complex at  $\alpha$  and Vietoris-Rips complex of L holds, for any  $\epsilon \in \mathbb{R}^+$  and  $\alpha \ge 2\epsilon$ .

 $R_{\alpha/3}(L) \subseteq LW_{\alpha}(P,L) \subseteq R_{3\alpha}(L)$ 

#### Theorem (Persistent diagram approximation)

If L is an  $\epsilon$ -net of the point cloud P the persistence diagram  $Dgm(\mathcal{LW}_{c+2\epsilon}(L))$  of the filtration  $(\mathcal{LW}(L))_{c+2\epsilon}$  induced by L is a 3-approximation to the diagram  $Dgm(\mathcal{R}_{c+2\epsilon}(L))$  of the Vietoris-Rips filtration  $(\mathcal{R}(L))_{c+2\epsilon}$  induced by L, for  $\epsilon \in \mathbb{R}^+$  and  $c \geq 0$ .

#### Corollary

If L is an  $\epsilon$ -net of the point cloud P, the bottleneck distance between the logarithm-scale persistence diagrams  $Dgm(\log \mathcal{LW}_{c+2\epsilon}(L))$  and  $Dgm(\log \mathcal{R}_{c+2\epsilon}(L))$  is at most log(3), for  $\epsilon \in \mathbb{R}^+$  and c > 0.

#### Lemma (Interleaving)

If L is an  $\epsilon$ -net of the vertex set V, the following interleaving of lazy witness complex at  $\alpha$  and Vietoris-Rips complex of L holds, for any  $\epsilon \in \mathbb{R}^+$  and  $\alpha \ge 2\epsilon$ 

 $R_{\alpha/3}(L) \subseteq LW_{\alpha}(V,L) \subseteq R_{3\alpha}(L)$ 

Image: A math a math

May 25, 2022

12/22

The main theorem and its corollary follows.

How good are the landmarks? Does the subspace (point cloud sample, subgraph) induced by  $\epsilon$ -net representative of the actual point cloud or graph data?

#### Point cloud

The Hausdorff distance between the point cloud P and its  $\epsilon$ -net  $L \subseteq P$  is at most  $\epsilon$ .

### Graph

The Hausdorff distance between  $(V, d_G)$  and its  $\epsilon$ -net induced subspace  $(L, d_L)$  is at most  $\epsilon$ .

*Number of landmarks:* For a given  $\epsilon$ , how many points (vertex) are there in the  $\epsilon$ -net?

### Graph

For a connected unweighted graph of diameter  $\Delta$ , there exists an  $\epsilon$ -net of size at most  $(\frac{\Delta}{\epsilon})^{O(\log \frac{|V|}{\epsilon})}$

## Algorithm for point cloud:: $(\epsilon, 2\epsilon)$ -net

Second landmark: Select u.a.r from the unmarked points in the  $(\epsilon, 2\epsilon)$  envelope of the current set of landmarks. And so on.

(日) (四) (문) (문) (문) (문)

## Practicality of the algorithms

The size of  $\epsilon$ -net generated by our algorithms are consistent with Krauthgamer's theoretical upper-bound (dataset: A sample from Torus surface).

Computational Complexity: For *n* points in  $\mathbb{R}^{D}$ 

- $\epsilon$ -net-rand:  $O(\frac{n}{\epsilon^D})$
- $\epsilon$ -net-maxmin:  $O(\frac{n^2}{\epsilon^D})$
- $(\epsilon, 2\epsilon)$ -net:  $O(\frac{n^2}{\epsilon^D})$

Image: A matrix

## Algorithm for Graph: Greedy $\epsilon$ -net

Figure 2: Greedy- $\epsilon$ -Net

Compute the  $\epsilon$ -cover sizes for each vertex.

At each step, select the vertex with the largest  $\epsilon$ -cover and mark the vertices covered by it, finally, update the  $\epsilon$ -cover sizes of non-marked vertices. Continue until all vertices are marked as covered.

Time-Complexity:  $O(n\hat{u}_{\epsilon} + (\frac{\Delta}{\epsilon})^{\log \frac{n}{\epsilon}})$  where  $\hat{u}_{\epsilon}$  is the cover-size of the vertex with the largest  $\epsilon$ -cover.

## Algorithm for Graph: Iterative $\epsilon$ -net

Figure 3: Iterative- $\epsilon$ -Net

Remarks: For a given  $\epsilon$ , we empirically found Greedy  $\epsilon$ -net to produce the least number of landmarks in general. However Greedy  $\epsilon$ -net is significantly inefficient compared to Iterative  $\epsilon$ -net.

Image: Image:

May 25, 2022

16/22

There are simplicial representations with better approximation guarantee than ours, but

- some of them are limited to point clouds.
- some uses simplicial maps which may not induce a filtration with canonical inclusion maps. As a result, one can not use well-studied matrix reduction algorithm to compute persistence any more.

▲□▶ ▲□▶ ▲□▶ ▲□▶ = ● ● ●

#### Existing approximations.

- Sparse-Čech filtration<sup>5</sup>:  $(1 + \epsilon)$   $\epsilon > 0$  w.r.t to Čech. (Does not induce a filtration)
- Sparse-Rips filtration<sup>6</sup>:  $(1 + 2\epsilon)$   $\epsilon < \frac{1}{3}$  w.r.t Vietoris-Rips.
- Simplicial Batch-collapse (Simba)<sup>7</sup>:  $(3 + \frac{2}{\epsilon-1})$   $\epsilon > 1$  w.r.t Vietoris-Rips (for point cloud only).
- $\epsilon$ -net induced lazy witness:  $3 + 2\epsilon$   $\epsilon > 0$  w.r.t Vietoris-Rips on the whole dataset. Works for point cloud and graphs.

<sup>5</sup>M. Kerber and R. Sharathkumar. "Approximate Čech complex in low and high dimensions". In: International Symposium on Algorithms and Computation. 2013.
 <sup>6</sup>Sheehy, "Linear-size approximations to the Vietoris–Rips filtration".
 <sup>7</sup>Tamal K Dey, D. Shi, and Y. Wang. "Simba: An efficient tool for approximating rips-filtration persistence via simplicial batch collapse". In: Journal of Experimental Algorithmics (JEA) (2019).

We want to use  $\epsilon$ -net

- to obtain better approximate guarantees.
- to investigate, compare and unify approximation schemes for Vietoris-Rips representations such as Sparse-Rips and Simba.

◆□▶ ◆御▶ ◆臣▶ ◆臣▶ ―臣 … のへで

To prove the first inclusion  $R_{\alpha/3}(L) \subseteq LW_{\alpha}(P,L)$ ,

- consider a k-simplex  $\sigma_k = [x_0 x_1 \cdots x_k] \in R_{\alpha/3}(L)$ .
- e For any edge [x<sub>i</sub>x<sub>j</sub>] ∈ σ<sub>k</sub>, let w' be the point in P that is nearest to the vertices of [x<sub>i</sub>x<sub>j</sub>] and wlog, let that vertex be x<sub>j</sub>.
- Since w' is the nearest neighbour of  $x_j$ ,  $d(w', x_j) \le \epsilon \le \frac{\alpha}{2}$  (as  $d(L, P) \le \epsilon$ ).
- Since  $[x_i x_j] \in R_{\alpha/3}$ ,  $d(x_i, x_j) \le \frac{\alpha}{3} < \frac{\alpha}{2}$ . By triangle inequality,  $d(w', x_i) \le \frac{\alpha}{2} + \frac{\alpha}{2} \le \alpha$ .
- Therefore x<sub>i</sub> is within distance α from w'. The α-neighbourhood of point w' contains both x<sub>i</sub> and x<sub>j</sub>. Since d(w', L) ≥ 0, the (d(w', L) + α)-neighbourhood of w' also contains x<sub>i</sub>, x<sub>j</sub>. Therefore, [x<sub>i</sub>x<sub>j</sub>] is an edge in LW<sub>α</sub>(P, L).
- Since the argument is true for any  $x_i, x_j \in \sigma_k$ , the k-simplex  $\sigma_k \in LW_{\alpha}(P, L)$ .

To prove the second inclusion  $LW_{\alpha}(P, L, 1) \subseteq R_{3\alpha}(L)$ 

• consider a k-simplex  $\sigma_k = [x_0 x_1 \cdots x_k] \in LW_{\alpha}(P, L).$ 

- By definition of lazy witness complex, ∀[x<sub>i</sub>x<sub>j</sub>] ∈ σ<sub>k</sub> there is a witness w ∈ P such that, the (d(w, L) + α)-neighbourhood of w contains both x<sub>i</sub> and x<sub>j</sub>.
- e Hence, d(w, x<sub>i</sub>) ≤ d(w, L) + α ≤ ε + α ≤ 3α/2. By the same argument, d(w, x<sub>j</sub>) ≤ 3α/2.
- By triangle inequality,  $d(x_i, x_j) \leq 3\alpha$ . Therefore,  $[x_i x_j]$  is an edge in  $R_{3\alpha}(L)$ .
- Since the argument is true for any  $x_i, x_j \in \sigma_k$ , the k-simplex  $\sigma_k \in R_{3\alpha}(L)$ .

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

# On computational infeasiblity of Čech complex: miniball algorithm

- One can run minimal algorithm to find the minimum enclosing radius of a simplex  $\sigma$ . For a given  $\sigma$ , that radius will give the offset  $\alpha$  where  $\sigma$  appears first.
- Fastest miniball algorithm runs in  $O(|\sigma|)$  time. (note that, the offset for  $\sigma$  can be found in constant time for Vietoris-rips complex if the complex is constructed dimension by dimension)
- However to run miniball algorithm one still needs to enumerate  $\sigma$  first, rendering the Čech filtration computation to be at least twice as slow as corresponding Vietoris-Rips filtration.

# Relation to Maxmin and Random Landmark Selection Algorithms

- Given the number of landmarks K > 1, the set of landmarks selected by the algorithm random/maxmin is  $\delta$ -sparse where  $\delta$  is the minimum of the pairwise distances among the landmarks.
- The choice of K may not necessarily make the landmarks a  $\delta$ -sample of the point cloud.

The topological approximation guarantee is

• with respect to the Vietoris-Rips complex on  $\epsilon$ -net landmarks chosen from a point-cloud input.

Next up -

- Better guarantee w.r.t Vietoris-Rips complex on point-cloud:-
  - Improved the approximation guarantee from 3-approximation of  $R_{\alpha}(L)$  to  $\frac{3\log(c)}{2}$ -approximation of  $R_{\alpha}(P)$  for  $c \geq 2$ .
- Graph data <sup>9</sup>:-
  - Defined  $\epsilon$ -net for graphs.
  - Devised algorithms for computing  $\epsilon$ -net of graphs.
  - Potential applications: Graph clustering, Graph visualization, Graph classification.
- Comparison with Sparse-Rips and Graph Induced filtration (A weakness!).
